INTRODUCTION TO THE ARM INSTRUCTION SET

INTRODUCTION TO THE ARM INSTRUCTION SET

Different ARM architecture revisions support different instructions. However, new revisions usually add instructions and remain backwardly compatible. Code you write for architecture ARMv4T should execute on an ARMv5TE processor.

The following Table provides a complete list of ARM instructions available in the *ARMv5E instruction set architecture (ISA)*. This ISA includes all the core ARM instructions as well as some of the newer features in the ARM instruction set.

Mnemonics	ARM ISA	Description	
ADC	v1	add two 32-bit values and carry	
ADD	v1	add two 32-bit values	
AND	v1	logical bitwise AND of two 32-bit values	
В	v1	branch relative $+/-32$ MB	
BIC	v1	logical bit clear (AND NOT) of two 32-bit values	
ВКРТ	v 5	breakpoint instructions	
BL	v1	relative branch with link	
BLX	v 5	branch with link and exchange	
ВΧ	v4T	branch with exchange	
CDP CDP2	v2 v5	coprocessor data processing operation	
CLZ	v 5	count leading zeros	
CMN	v1	compare negative two 32-bit values	
CMP	v1	compare two 32-bit values	
EOR	v1	logical exclusive OR of two 32-bit values	
LDC LDC2	v2 v5	load to coprocessor single or multiple 32-bit values	
LDM	v1	load multiple 32-bit words from memory to ARM registers	
LDR	v1 v4 v5E	load a single value from a virtual address in memory	

Table: ARM Instruction Set

Mnemonics	ARM ISA	Description
MCR MCR2 MCRR MLA MOV MRC MRC2 MRRC MRS MSR MUL MVN	v2 v1	move to coprocessor from an ARM register or registers multiply and accumulate 32-bit values move a 32-bit value into a register move to ARM register or registers from a coprocessor move to ARM register from a status register (<i>cpsr</i> or <i>spsr</i>) move to a status register (<i>cpsr</i> or <i>spsr</i>) from an ARM register multiply two 32-bit values move the logical NOT of 32-bit value into a register

Mnemonics	ARM ISA	Description
ORR	v1	logical bitwise OR of two 32-bit values
PLD	v5E	preload hint instruction
QADD	v5E	signed saturated 32-bit add
QDADD	v5E	signed saturated double and 32-bit add
QDSUB	v5E	signed saturated double and 32-bit subtract
QSUB	v5E	signed saturated 32-bit subtract
RSB	v 1	reverse subtract of two 32-bit values
RSC	v 1	reverse subtract with carry of two 32-bit integers
SBC	v 1	subtract with carry of two 32-bit values
SMLA <i>xy</i>	v5E	signed multiply accumulate instructions $((16 \times 16) + 32 = 32$ -bit)
SMLAL	v3M	signed multiply accumulate long $((32 \times 32) + 64 = 64$ -bit)
SMLAL <i>xy</i>	v5E	signed multiply accumulate long $((16 \times 16) + 64 = 64$ -bit)
SMLAWy	v5E	signed multiply accumulate instruction (($(32 \times 16) \gg 16$) + 32 = 32-bit)
SMULL	v3M	signed multiply long $(32 \times 32 = 64$ -bit)

Mnemonics	ARM ISA	Description	
SMULxy	v5E	signed multiply instructions $(16 \times 16 = 32$ -bit)	
SMULWy	v5E	signed multiply instruction $((32 \times 16) \gg 16 = 32$ -bit)	
STC STC2	v2 v5	store to memory single or multiple 32-bit values from coprocessor	
STM	v1	store multiple 32-bit registers to memory	
STR	v1 v4 v5E	store register to a virtual address in memory	
SUB	v1	subtract two 32-bit values	
SWI	v1	software interrupt	
SWP	v2a	swap a word/byte in memory with a register, without interruption	
TEQ	v1	test for equality of two 32-bit values	
TST	v 1	test for bits in a 32-bit value	
UMLAL	v3M	unsigned multiply accumulate long $((32 \times 32) + 64 = 64$ -bit)	
UMULL	v3M	unsigned multiply long $(32 \times 32 = 64$ -bit)	

In the following sections, the hexadecimal numbers are represented with the prefix 0x and binary numbers

with the prefix 0b. The examples follow this format:

PRE <pre-conditions>

<instruction/s>

POST <post-conditions>

In the pre- and post-conditions, memory is denoted as

mem<data_size>[address]

This refers to *data_size* bits of memory starting at the given byte address. For example, *mem32[1024]* is the 32-bit value starting at address 1 KB.

ARM instructions process data held in registers and memory is accessed only with load and store instructions.

ARM instructions commonly take two or three operands. For instance, the ADD instruction below adds the two values stored in registers r1 and r2 (the source registers). It writes the result to register r3 (the destination register).

Instruction	Destination	Source	Source
Syntax	register (<i>Rd</i>)	register 1 (<i>Rn</i>)	register 2 (<i>Rm</i>)
ADD r3, r1, r2	r3	r1	r2

ARM instructions classified as—data processing instructions, branch instructions, load-store instructions, software interrupt instruction, and program status register instructions.

DATA PROCESSING INSTRUCTIONS:

The data processing instructions manipulate data within registers. They are-

✓ move instructions, arithmetic instructions, logical instructions, comparison instructions, and multiply instructions.

Most data processing instructions can process one of their operands using the barrel shifter.

If you use the S suffix on a data processing instruction, then it updates the flags in the cpsr.

Move and logical operations update the carry flag C, negative flag N, and zero flag Z.

- \circ The *C* flag is set from the result of the barrel shift as the last bit shifted out.
- The *N* flag is set to bit 31 of the result.
- The Z flag is set if the result is zero.

MOVe Instructions:

Move instruction copies N into a destination register Rd, where N is a register or immediate value. This instruction is useful for setting initial values and transferring data between registers.

Syntax: <instruction>{<cond>}{S} Rd, N

MOV	Move a 32-bit value into a register	Rd = N
MVN	move the NOT of the 32-bit value into a register	$Rd = \sim N$

Example: This example shows a simple move instruction. The MOV instruction takes the contents of register r5 and copies them into register r7, in this case, taking the value 5, and overwriting the value 8 in register r7.

```
PRE r5 = 5
r7 = 8
MOV r7, r5; let r7 = r5
POST r5 = 5
r7 = 5
```

Barrel Shifter:

In above Example, we showed a MOV instruction where N is a simple register. But N can be more than just a register or immediate value; it can also be a register Rm that has been preprocessed by the barrel shifter prior to being used by a data processing instruction.

- ✓ Data processing instructions are processed within the arithmetic logic unit (ALU).
- ✓ A unique and powerful feature of the ARM processor is the ability to shift the 32-bit binary pattern in one of the source registers left or right by a specific number of positions before it enters the ALU.
- \checkmark Pre-processing or shift occurs within the cycle time of the instruction.
 - This shift increases the power and flexibility of many data processing operations.
 - This is particularly useful for loading constants into a register and achieving fast multiplies or division by a power of 2.
- ✓ There are data processing instructions that do not use the barrel shift, for example, the MUL (multiply), CLZ (count leading zeros), and QADD (signed saturated 32-bit add) instructions.

Figure: Barrel Shifter and ALU

- \checkmark Figure shows the data flow between the ALU and the barrel shifter.
- \checkmark Register *Rn* enters the ALU without any pre- processing of registers.
- ✓ We apply a logical shift left (LSL) to register Rm before moving it to the destination register. This is the same as applying the standard *C* language shift operator « to the register.
- ✓ The MOV instruction copies the shift operator result *N* into register *Rd*. *N* represents the result of the LSL operation described in the following Table.

15CS44

Mnemonic	Description	Shift	Result	Shift amount y
LSL	logical shift left	xLSL y	$x \ll y$	#0–31 or <i>Rs</i>
LSR	logical shift right	xLSR y	$(unsigned)x \gg y$	#1–32 or <i>Rs</i>
ASR	arithmetic right shift	xASR y	$(signed)x \gg y$	#1–32 or Rs
ROR	rotate right	x ROR y	$((\text{unsigned})x \gg y) \mid (x \ll (32 - y))$	#1–31 or Rs
RRX	rotate right extended	xRRX	$(c \text{ flag} \ll 31) \mid ((\text{unsigned})x \gg 1)$	none

Table: Barrel Shifter Operations

Note: x represents the register being shifted and y represents the shift amount.

✓ The five different shift operations that you can use within the barrel shifter are summarized in the above Table.

*PRE r*5 = 5

r7 = 8

MOV r7, r5, *LSL* #2 ; *let* r7 = r5*4 = (r5 << 2)

*POST r*5 = 5

*r*7 = 20

- \checkmark The above example multiplies register *r5* by four and then places the result into register *r7*.
- ✓ The following Figure illustrates a logical shift left by one.

Figure: Logical Shift Left by One

✓ For example, the contents of bit 0 are shifted to bit 1. Bit 0 is cleared. The C flag is updated with the last bit shifted out of the register. This is bit (32 - y) of the original value, where y is the shift amount. When y is greater than one, then a shift by y positions is the same as a shift by one position executed y times.

Example: This example of a MOVS instruction shifts register r1 left by one bit. This multiplies register r1 by a value 2^{1} . As you can see, the C flag is updated in the *cpsr* because the S suffix is present in the instruction mnemonic.

 PRE
 $cpsr = nzcvqiFt_USER$

 r0 = 0x00000000

 r1 = 0x80000004

 MOVS
 r0, r1, LSL #1

 POST
 $cpsr = nzCvqiFt_USER$

 r0 = 0x0000008 r1 = 0x80000004

The following Table lists the syntax for the different barrel shift operations available on data processing instructions. The second operand N can be an immediate constant preceded by #, a register value Rm, or the value of Rm processed by a shift.

N shift operations	Syntax	
Immediate	#immediate	
Register	Rm	
Logical shift left by immediate	Rm, LSL #shift imm	
Logical shift left by register	Rm, LSL Rs	
Logical shift right by immediate	Rm, LSR #shift imm	
Logical shift right with register	Rm, LSR Rs	
Arithmetic shift right by immediate	Rm, ASR #shift imm	
Arithmetic shift right by register	Rm, ASR Rs	
Rotate right by immediate	Rm, ROR #shift imm	
Rotate right by register	Rm, ROR Rs	
Rotate right with extend	Rm, RRX	

Table: Barrel Shifter Operation Syntax for data Processing Instructions

Arithmetic Instructions:

The arithmetic instructions implement addition and subtraction of 32-bit signed and unsigned values.

ADC	add two 32-bit values and carry	Rd = Rn + N + carry
ADD	add two 32-bit values	Rd = Rn + N
RSB	reverse subtract of two 32-bit values	Rd = N - Rn
RSC	reverse subtract with carry of two 32-bit values	Rd = N - Rn - !(carry flag)
SBC	subtract with carry of two 32-bit values	Rd = Rn - N - !(carry flag)
SUB	subtract two 32-bit values	Rd = Rn - N

Syntax: <instruction>{<cond>}{S} Rd, Rn, N

N is the result of the shifter operation.

Example: The following simple subtract instruction subtracts a value stored in register r^2 from a value stored in register r^1 . The result is stored in register r^0 .

 PRE
 r0 = 0x00000000

 r1 = 0x00000002

 r2 = 0x00000001

 SUB r0, r1, r2

 POST
 r0 = 0x00000001

Example: The following reverse subtract instruction (RSB) subtracts r1 from the constant value #0, writing the result to r0. You can use this instruction to negate numbers.

PRE r0 = 0x00000000r1 = 0x00000077**RSB** r0, r1, #0; Rd = 0x0 - r1**POST** r0 = -r1 = 0xffffff89

Example: The SUBS instruction is useful for decrementing loop counters. In this example, we subtract the immediate value one from the value one stored in register r1. The result value zero is written to register r1. The *cpsr* is updated with the ZC flags being set.

PRE $cpsr = nzcvqiFt_USER$ r1 = 0x00000001SUBS r1, r1, #1**POST** $cpsr = nZCvqiFt_USER$ r1 = 0x00000000

Using the Barrel Shifter with Arithmetic Instructions:

The wide range of second operand shifts available on arithmetic and logical instructions is a very powerful feature of the ARM instruction set. The following Example illustrates the use of the inline barrel shifter with an arithmetic instruction. The instruction multiplies the value stored in register r1 by three. Example: Register r1 is first shifted one location to the left to give the value of twice r1. The ADD instruction then adds the result of the barrel shift operation to register r1. The final result transferred into register r0 is equal to three times the value stored in register r1.

 PRE
 r0 = 0x00000000

 r1 = 0x00000005

 ADD
 r0, r1, r1, LSL #1

 POST
 r0 = 0x0000000f

 r1 = 0x00000005

 MAHESH PRASANNA K., VCET, PUTTUR

7

15CS44

Logical Instructions:

Logical instructions perform bitwise logical operations on the two source registers.

```
Syntax: <instruction>{<cond>}{S} Rd, Rn, N
```

AND	logical bitwise AND of two 32-bit values	Rd = Rn & N
ORR	logical bitwise OR of two 32-bit values	$Rd = Rn \mid N$
EOR	logical exclusive OR of two 32-bit values	$Rd = Rn^{\wedge}N$
BIC	logical bit clear (AND NOT)	$Rd = Rn \& \sim N$

Example: This example shows a logical OR operation between registers r1 and r2. Register r0 holds the result.

PREr0 = 0x00000000r1 = 0x02040608r2 = 0x10305070ORRr0, r1, r2POSTr0 = 0x12345678

Example: This example shows a more complicated logical instruction called BIC, which carries out a logical bit clear.

PRE r1 = 0b1111r2 = 0b0101BIC r0, r1, r2 **POST** r0 = 0b1010

This is equivalent to - Rd = Rn AND NOT (N)

In this example, register r^2 contains a binary pattern where every binary 1 in r^2 clears a corresponding bit location in register r^1 .

This instruction is particularly useful when clearing status bits and is frequently used to change interrupt masks in the *cpsr*.

<u>NOTE</u>: The logical instructions update the *cpsr* flags only if the S suffix is present. These instructions can use barrel-shifted second operands in the same way as the arithmetic instructions.

Comparison Instructions:

- \checkmark The comparison instructions are used to compare or test a register with a 32-bit value.
- \checkmark They update the *cpsr* flag bits according to the result, but do not affect other registers.

After the bits have been set, the information can then be used to change program flow by using conditional execution.

 \checkmark It is not required to apply the S suffix for comparison instructions to update the flags.

```
Syntax: <instruction>{<cond>} Rn, N
```

CMN	compare negated	flags set as a result of $Rn + N$
CMP	compare	flags set as a result of $Rn - N$
TEQ	test for equality of two 32-bit values	flags set as a result of $Rn \wedge N$
TST	test bits of a 32-bit value	flags set as a result of $Rn \& N$

N is the result of the shifter operation.

Example: This example shows a CMP comparison instruction. You can see that both registers, r0 and r9, are equal before executing the instruction. The value of the Z flag prior to execution is 0 and is represented by a lowercase z. After execution the Z flag changes to 1 or an uppercase Z. This change indicates equality.

PRE $cpsr = nzcvqiFt_USER$ r0 = 4r9 = 4*CMP* r0, r9**POST** $cpsr = nZcvqiFt_USER$

- ✓ The CMP is effectively a subtract instruction with the result discarded; similarly the TST instruction is a logical AND operation, and TEQ is a logical exclusive OR operation.
- \checkmark For each, the results are discarded but the condition bits are updated in the *cpsr*.
- ✓ It is important to understand that comparison instructions only modify the condition flags of the *cpsr* and do not affect the registers being compared.

Multiply Instructions:

The multiply instructions multiply the contents of a pair of registers and, depending upon the instruction, accumulate the results in with another register.

The long multiplies accumulate onto a pair of registers representing a 64-bit value. The final result is placed in a destination register or a pair of registers.

```
Syntax: MLA{<cond>}{S} Rd, Rm, Rs, Rn
    MUL{<cond>}{S} Rd, Rm, Rs
```

MLA	multiply and accumulate	$Rd = (Rm^*Rs) + Rn$
MUL	multiply	$Rd = Rm^*Rs$

SMLAL	signed multiply accumulate long	[RdHi, RdLo] = [RdHi, RdLo] + (Rm * Rs)
SMULL	signed multiply long	$[RdHi, RdLo] = Rm^*Rs$
UMLAL	unsigned multiply accumulate long	[RdHi, RdLo] = [RdHi, RdLo] + (Rm * Rs)
UMULL	unsigned multiply long	$[RdHi, RdLo] = Rm^*Rs$

Syntax: <instruction>{<cond>}{S} RdLo, RdHi, Rm, Rs

The number of cycles taken to execute a multiply instruction depends on the processor implementation. For some implementations the cycle timing also depends on the value in *Rs*.

Example: This example shows a simple multiply instruction that multiplies registers r1 and r2 together and places the result into register r0. In this example, register r1 is equal to the value 2, and r2 is equal to 2. The result, 4, is then placed into register r0.

 PRE
 r0 = 0x00000000

 r1 = 0x00000002

 r2 = 0x00000002

 MUL r0, r1, r2 ; r0 = r1*r2

 POST
 r0 = 0x00000004

 r1 = 0x0000002

 r2 = 0x0000002

The long multiply instructions (SMLAL, SMULL, UMLAL, and UMULL) produce a 64-bit result. The result is too large to fit a single 32-bit register so the result is placed in two registers labeled *RdLo* and *RdHi*. *RdLo* holds the lower 32 bits of the 64-bit result, and *RdHi* holds the higher 32 bits of the 64-bit result. The following shows an example of a long unsigned multiply instruction.

Example: The instruction multiplies registers r^2 and r^3 and places the result into register r^0 and r^1 . Register r^0 contains the lower 32 bits, and register r^1 contains the higher 32 bits of the 64-bit result.

PRE	r0 = 0x00000000	
	r1 = 0x00000000	
	r2 = 0xf000002	
	r3 = 0x00000002	
UMUI	LL r0, r1, r2, r3	; [r1,r0] = r2*r3
POST	r0 = 0xe0000004	; = RdLo
	r1 = 0x00000001	; = RdHi

BRANCH INSTRUCTIONS:

A branch instruction changes the flow of execution or is used to call a routine. This type of instruction allows programs to have subroutines, if-then-else structures, and loops.

The change of execution flow forces the program counter pc to point to a new address. The ARMv5E instruction set includes four different branch instructions.

Syntax: B{<cond>} label BL{<cond>} label BX{<cond>} Rm BLX{<cond>} label | Rm

В	branch	pc = label
BL	branch with link	<pre>pc = label lr = address of the next instruction after the BL</pre>
BX	branch exchange	<pre>pc = Rm & Oxfffffffe, T = Rm & 1</pre>
BLX	branch exchange with link	<pre>pc = label, T = 1 pc = Rm & 0xfffffffe, T = Rm & 1 lr = address of the next instruction after the BLX</pre>

- \checkmark The address *label* is stored in the instruction as a signed *pc*-relative offset and must be within approximately 32 MB of the branch instruction.
- \checkmark T refers to the Thumb bit in the *cpsr*. When instructions set T, the ARM switches to Thumb state.

Example: This example shows a forward and backward branch. Because these loops are address specific, we do not include the pre- and post-conditions. The forward branch skips three instructions. The backward branch creates an infinite loop.

B forward ADD r1, r2, #4 ADD r0, r6, #2 ADD r3, r7, #4 forward

SUB r1, r2, #4

backward

ADD r1, r2, #4 SUB r1, r2, #4 ADD r4, r6, r7 B backward

MAHESH PRASANNA K., VCET, PUTTUR

In this example, *forward* and *backward* are the labels. The branch labels are placed at the beginning of the line and are used to mark an address that can be used later by the assembler to calculate the branch offset.

✓ The branch with link, or BL, instruction is similar to the B instruction but overwrites the link register *lr* with a return address. It performs a subroutine call.

Example: This example shows a simple fragment of code that, branches to a subroutine using the BL instruction. To return from a subroutine, you copy the link register to the pc.

BL	subroutine	; branch to subroutine	
<i>CMP r1, #5</i>		; compare r1 with 5	
<i>MOVEQ r1, #0</i>		; if $(r1==5)$ then $r1=0$	

subroutine

<subroutine code> MOV pc, lr

; return by moving pc = lr

- ✓ The branch exchange (BX) and branch exchange with link (BLX) are the third type of branch instruction.
- ✓ The BX instruction uses an absolute address stored in register Rm. It is primarily used to branch to and from Thumb code. The *T* bit in the *cpsr* is updated by the least significant bit of the branch register.
- ✓ Similarly the BLX instruction updates the *T* bit of the *cpsr* with the least significant bit and additionally sets the link register with the return address.

LOAD-STORE INSTRUCTIONS:

Load-store instructions transfer data between memory and processor registers. There are three types of load-store instructions: single-register transfer, multiple-register transfer, and swap.

Single-Register Transfer:

- \checkmark These instructions are used for moving a single data item in and out of a register.
- ✓ The data types supported are signed and unsigned words (32-bit), half-words (16-bit), and bytes.

Here are the various load-store single-register transfer instructions.

Syntax: <LDR|STR>{<cond>}{B} Rd,addressing¹ LDR{<cond>}SB|H|SH Rd, addressing² STR{<cond>}H Rd, addressing²

15CS44

MICROPROCESSORS AND MICROCONTROLLERS

LDR	load word into a register	Rd <- mem32[address]
STR	save byte or word from a register	Rd -> mem32[address]
LDRB	load byte into a register	Rd <- mem8[address]
STRB	save byte from a register	Rd -> mem8[address]

LDRH	load halfword into a register	Rd <- mem16[address]
STRH	save halfword into a register	Rd -> mem16[address]
LDRSB	load signed byte into a register	Rd <- SignExtend (mem8[address])
LDRSH	load signed halfword into a register	Rd <- SignExtend (mem16[address])

- ✓ LDR and STR instructions can load and store data on a boundary alignment that is the same as the data type size being loaded or stored.
 - For example, LDR can only load 32-bit words on a memory address that is a multiple of four bytes—0, 4, 8, and so on.

Example: This example shows a load from a memory address contained in register r1, followed by a store back to the same address in memory.

; load register r0 with the contents of ; the memory address pointed to by register ; r1. ; LDR r0, [r1] ; = LDR r0, [r1, #0] ; ; store the contents of register r0 to ; the memory address pointed to by ; register r1.

;

```
STR r0, [r1] ; = STR r0, [r1, #0]
```

The first instruction loads a word from the address stored in register r1 and places it into register r0. The second instruction goes the other way by storing the contents of register r0 to the address contained in register r1. The offset from register r1 is zero. Register r1 is called the *base address register*.

Single-Register Load-Store Addressing Modes:

The ARM instruction set provides different modes for addressing memory. These modes incorporate one of the indexing methods: preindex with writeback, preindex, and postindex.

Table: Index Methods

Index method	Data	Base address register	Example
Preindex with writeback	mem[base + offset]	base + offset	LDR r0,[r1,#4]!
Preindex	mem[base + offset]	not updated	LDR r0,[r1,#4]
Postindex	mem[base]	base + offset	LDR r0,[r1],#4

Note: ! indicates that the instruction writes the calculated address back to the base address register.

- ✓ *Preindex with writeback* calculates an address from a base register plus address offset and then updates that address base register with the new address.
- ✓ Preindex offset is the same as the preindex with writeback but does not update the address base register.
 - The preindex mode is useful for accessing an element in a data structure.
- ✓ *Postindex* only updates the address base register after the address is used.
 - The postindex and preindex with writeback modes are useful for traversing an array.

Example:

PRE

r0 = 0x00000000 r1 = 0x00090000 mem32[0x00009000] = 0x01010101mem32[0x00009004] = 0x02020202

LDR r0, [*r1*, #4]!

Preindexing with writeback:

POST(1) r0 = 0x02020202

r1 = 0x00009004

LDR r0, [r1, #4]

Preindexing:

POST(2) r0 = 0x02020202r1 = 0x00009000

LDR r0, [r1], #4

Postindexing:

POST(3) r0 = 0x01010101

r1 = 0x00009004

✓ The above Example used a preindex method. This example shows how each indexing method affects the address held in register r1, as well as the data loaded into register r0.

The addressing modes available with a particular load or store instruction depend on the instruction class. The following Table shows the addressing modes available for load and store of a 32-bit word or an unsigned byte.

Addressing ¹ mode and index method	Addressing ¹ syntax	
Preindex with immediate offset Preindex with scaled register offset Preindex with scaled register offset Preindex writeback with immediate offset Preindex writeback with register offset Preindex writeback with scaled register offset Immediate postindexed Register postindex	<pre>[Rn, #+/-offset_12] [Rn, +/-Rm] [Rn, +/-Rm, shift #shift_imm] [Rn, #+/-offset_12]! [Rn, +/-Rm]! [Rn, +/-Rm, shift #shift_imm]! [Rn], #+/-offset_12 [Rn], +/-Rm</pre>	
Scaled register postindex	<pre>[Rn], +/-Rm, shift #shift_imm</pre>	

Table: Single-Register Load-Store Addressing, Word or Unsigned Byte

- ✓ A signed offset or register is denoted by "+/-", identifying that it is either a positive or negative offset from the base address register Rn. The base address register is a pointer to a byte in memory, and the offset specifies a number of bytes.
- ✓ Immediate means the address is calculated using the base address register and a 12-bit offset encoded in the instruction.
- ✓ Register means the address is calculated using the base address register and a specific register's contents.
- \checkmark Scaled means the address is calculated using the base address register and a barrel shift operation.

The following Table provides an example of the different variations of the LDR instruction.

	Instruction	r0 =	r1 + =
Preindex with	LDR r0,[r1,#0x4]!	mem32[r1+0x4]	0x4
writeback	LDR r0,[r1,r2]!	mem32[r1+r2]	r2
	LDR r0,[r1,r2,LSR#0x4]!	mem32[r1+(r2 LSR 0x4)]	(r2 LSR 0x4)
Preindex	LDR r0,[r1,#0x4]	mem32[r1+0x4]	not updated
	LDR r0,[r1,r2]	mem32[r1+r2]	not updated
Postindex	LDR r0,[r1,-r2,LSR #0x4]	mem32[r1-(r2 LSR 0x4)]	<i>not updated</i>
	LDR r0,[r1],#0x4	mem32[r1]	0x4
	LDR r0,[r1],r2	mem32[r1]	r2
	LDR r0,[r1],r2,LSR #0x4	mem32[r1]	(r2 LSR 0x4)

Table: Examples of LDR Instructions using Different Addressing Modes

The following Table shows the addressing modes available on load and store instructions using 16-bit halfword or signed byte data.

Table: Single-Register Load-Store Addressing, Halfword, Signed Halfword, Signed Byte and Doubleword

Addressing ² mode and index method	Addressing ² syntax	
Preindex immediate offset	[Rn, #+/-offset_8]	
Preindex register offset	[Rn, +/-Rm]	
Preindex writeback immediate offset	[Rn, #+/-offset_8]!	
Preindex writeback register offset	[Rn, +/-Rm]!	
Immediate postindexed	[Rn], #+/-offset_8	
Register postindexed	[Rn], +/-Rm	

These operations cannot use the barrel shifter. There are no STRSB or STRSH instructions since STRH stores both a signed and unsigned halfword; similarly STRB stores signed and unsigned bytes. The following Table shows the variations for STRH instructions.

Table: Variations of STRH Instructions			
	Instruction	Result	r1 + =
Preindex with writeback	STRH r0,[r1,#0x4]!	mem16[r1+0x4]=r0	0x4
	STRH r0,[r1,r2]!	mem16[r1+r2]=r0	r2
Preindex	STRH r0,[r1,#0x4]	mem16[r1+0x4]=r0	not updated
	STRH r0,[r1,r2]	mem16[r1+r2]=r0	not updated
Postindex	STRH r0,[r1],#0x4	mem16[r1]=r0	0x4

Tables Variations of STDU Instructions

Multiple-Register Transfer:

- \checkmark Load-store multiple instructions can transfer multiple registers between memory and the processor in a single instruction.
- \checkmark The transfer occurs from a base address register *Rn* pointing into memory.
 - Multiple-register transfer instructions are more efficient from single-register transfers for

mem16[r1]=r0

- moving blocks of data around memory and
- saving and restoring context and stacks.
- ✓ Load-store multiple instructions can increase interrupt latency.

STRH r0, [r1], r2

- ✓ ARM implementations do not usually interrupt instructions while they are executing.
 - For example, on an ARM7 a load multiple instruction takes 2 + Nt cycles, where N is the number of registers to load and t is the number of cycles required for each sequential access to memory.
- \checkmark If an interrupt has been raised, then it has no effect until the load-store multiple instruction is complete.

MAHESH PRASANNA K., VCET, PUTTUR

r2

Compilers, such as *armcc*, provide a switch to control the maximum number of registers being transferred on a load-store, which limits the maximum interrupt latency.

Syntax: <LDM|STM>{<cond>}<addressing mode> Rn{!},<registers>{^}

LDM	load multiple registers	$\{Rd\}^{*N} <- mem32[start address + 4^*N] optional Rn updated$
STM	save multiple registers	$\{Rd\}^{*N}$ -> mem32[start address + 4*N] optional Rn updated

The following Table shows the different addressing modes for the load-store multiple instructions. Here *N* is the number of registers in the list of registers.

Addressing mode	Description	Start address	End address	Rn!
IA	increment after	Rn	$Rn + 4^*N - 4$	$Rn + 4^*N$
IB	increment before	Rn + 4	$Rn + 4^*N$	$Rn + 4^*N$
DA	decrement after	$Rn - 4^*N + 4$	Rn	$Rn - 4^*N$
DB	decrement before	$Rn - 4^*N$	Rn-4	$Rn - 4^*N$

Table: Addressing Mode for Load-Store Multiple Instructions

✓ Any subset of the current bank of registers can be transferred to memory or fetched from memory.

✓ The base register Rn determines the source or destination address for a load-store multiple instruction. This register can be optionally updated following the transfer. This occurs when register Rn is followed by the ! character, similar to the single-register load-store using preindex with writeback.

Example: In this example, register r0 is the base register Rn and is followed by !, indicating that the register is updated after the instruction is executed. You will notice within the load multiple instruction that the registers are not individually listed. Instead the "-" character is used to identify a range of registers. In this case the range is from register r1 to r3 inclusive.

Each register can also be listed, using a comma to separate each register within "{" and "}" brackets.

r2 = 0x0000002

r3 = 0x0000003

The following Figure shows a graphical representation.

Figure: Pre-condition for LDMIA Instruction

- ✓ The base register r0 points to memory address 0x80010 in the PRE condition.
- ✓ Memory addresses 0x80010, 0x80014, and 0x80018 contain the values 1, 2, and 3 respectively.
- ✓ After the load multiple instruction executes, registers r1, r2, and r3 contain these values as shown in the following Figure.

Figure: Post Condition for LDMIA Instruction

- \checkmark The base register *r0* now points to memory address 0x8001c after the last loaded word.
- ✓ Now replace the LDMIA instruction with a load multiple and increment before LDMIB instruction and use the same PRE conditions.
- ✓ The first word pointed to by register r0 is ignored and register r1 is loaded from the next memory location as shown in the following Figure.

Address pointer	Memory address	Data	
	0x80020	0x0000005	
$r\theta = 0x8001c \longrightarrow$	0x8001c	0x00000004	r3 = 0x00000004
	0x80018	0x0000003	$r^2 = 0 \times 00000003$
	0x80014	0x0000002	rI = 0x0000002
	0x80010	0x0000001	
	0x8000c	0x00000000	

Figure: Post Condition for LDMIB Instruction

- ✓ After execution, register r0 now points to the last loaded memory location. This is in contrast with the LDMIA example, which pointed to the next memory location.
- The decrement versions DA and DB of the load-store multiple instructions decrement the start address and then store to ascending memory locations.
- This is equivalent to descending memory but accessing the register list in reverse order.
- With the increment and decrement load multiples; you can access arrays forwards or backwards.
- They also allow for stack push and pull operations.

The following Table shows a list of load-store multiple instruction pairs.

Store Multiple	Load Multiple
STMIA	LDMDB
STMIB	LDMDA
STMDA	LDMIB
STMDB	LDMIA

Table: Load-Store Multiple Pairs when Base Update used

- If you use a store with base update, then the paired load instruction of the same number of registers will reload the data and restore the base address pointer.
- This is useful when you need to temporarily save a group of registers and restore them later.

Example: This example shows an STM *increment before* instruction followed by an LDM *decrement after* instruction.

PRE r0 = 0x00009000 r1 = 0x0000009 r2 = 0x0000008 r3 = 0x0000007 STMIB r0!, {r1-r3} MOV r1, #1 MOV r2, #2 MAHESH PRASANNA K., VCET, PUTTUR

```
MOV r3, \#3
PRE(2) r0 = 0x0000900c
r1 = 0x00000001
r2 = 0x00000002
r3 = 0x00000003
LDMDA r0!, \{r1-r3\}
POST r0 = 0x00009000
r1 = 0x0000009
r2 = 0x0000008
r3 = 0x0000007
```

The STMIB instruction stores the values 7, 8, 9 to memory. We then corrupt register r1 to r3. The LDMDA reloads the original values and restores the base pointer r0.

Example: We illustrate the use of the load-store multiple instructions with a block memory copy example. This example is a simple routine that copies blocks of 32 bytes from a source address location to a destination address location.

The example has two load-store multiple instructions, which use the same increment after addressing mode.

; r9 points to start of source data

; r10 points to start of destination data

; r11 points to end of the source

loop

; load 32 bytes from source and update r9 pointer

LDMIA r9!, {r0-r7}

; store 32 bytes to destination and update r10 pointer

STMIA r10!, {r0-r7} ; and store them

; have we reached the end

CMP r9, r11 BNE loop

- \checkmark This routine relies on registers r9, r10, and r11 being set up before the code is executed.
- ✓ Registers r9 and r11 determine the data to be copied, and register r10 points to the destination in memory for the data.
- ✓ LDMIA loads the data pointed to by register r9 into registers r0 to r7. It also updates r9 to point to the next block of data to be copied.
- ✓ STMIA copies the contents of registers r0 to r7 to the destination memory address pointed to by register r10. It also updates r10 to point to the next destination location.

CMP and BNE compare pointers *r*9 and *r*11 to check whether the end of the block copy has been reached.

- ✓ If the block copy is complete, then the routine finishes; otherwise the loop repeats with the updated values of register r9 and r10.
- The BNE is the branch instruction B with a condition mnemonic NE (not equal). If the previous compare instruction sets the condition flags to not equal, the branch instruction is executed.

The following Figure shows the memory map of the block memory copy and how the routine moves through memory.

Figure: Block Memory Copy in the Memory map

Theoretically this loop can transfer 32 bytes (8 words) in two instructions, for a maximum possible throughput of 46 MB/second being transferred at 33 MHz. These numbers assume a perfect memory system with fast memory.

Stock Operation: The ARM architecture uses the load-store multiple instructions to carry out stack operations.

- The *pop operation* (removing data from a stack) uses a load multiple instruction.
- The *push operation* (placing data onto the stack) uses a store multiple instruction.
- \checkmark When using a stack you have to decide whether the stack will grow up or down in memory.
 - A stack is either
 - ascending (A) stacks grow towards higher memory addresses or
 - *descending* (D) stacks grow towards lower memory addresses.
- ✓ When you use a *full stack* (*F*), the stack pointer *sp* points to an address that is the last used or full location (i.e., *sp* points to the last item on the stack).

If you use an *empty stack* (E) the *sp* points to an address that is the first unused or empty location (i.e., it points after the last item on the stack).

• There are number of load-store multiple addressing mode aliases available to support stack operations (see the following Table).

Addressing mode	Description	Рор	= LDM	Push	= STM
FA	full ascending	LDMFA	LDMDA	STMFA	STMIB
FD	full descending	LDMFD	LDMIA	STMFD	STMDB
EA	empty ascending	LDMEA	LDMDB	STMEA	STMIA
ED	empty descending	LDMED	LDMIB	STMED	STMDA

Table: Addressing Methods for Stack Operations

• Next to the *pop* column is the actual load multiple instruction equivalent.

- For example, a full ascending stack would have the notation FA appended to the load multiple instruction—LDMFA. This would be translated into an LDMDA instruction.
- ARM has specified an *ARM-Thumb Procedure Call Standard (ATPCS)* that defines how routines are called and how registers are allocated. In the ATPCS, stacks are defined as being full descending stacks. Thus, the LDMFD and STMFD instructions provide the *pop* and *push* functions, respectively.

Example: The STMFD instruction pushes registers onto the stack, updating the *sp*. The following Figure shows a *push* onto a full descending stack.

PRE	Address	Data	POST	Address	Data
	0x80018	0x0000001		0x80018	0x0000001
sp →	0x80014	0x0000002			0x0000002
	0x80010	Empty		0x80010	0x0000003
	0x8000c	Empty	sp →	0x8000c	0x0000002

Figure: STMFD Instruction – Full Stack push Operation

You can see that when the stack grows the stack pointer points to the last full entry in the stack.

 PRE
 r1 = 0x00000002

 r4 = 0x00000003

 sp = 0x00080014

 STMED sp!, {r1, r4}
 POST

 r1 = 0x00000002 r4 = 0x00000003

 sp = 0x00080008 sp = 0x00080008

- ✓ When handling a checked stack there are three attributes that need to be preserved: the stack base, the stack pointer, and the stack limit.
- \checkmark The stack base is the starting address of the stack in memory.
- ✓ The stack pointer initially points to the stack base; as data is pushed onto the stack, the stack pointer descends memory and continuously points to the top of stack. If the stack pointer passes the stack limit, then a stack overflow error has occurred.
- \checkmark Here is a small piece of code that checks for stack overflow errors for a descending stack:

; check for stack overflow

SUB sp, sp, #sizeCMP sp, r10BLLO _stack_overflow; condition

- ATPCS defines register *r10* as the stack limit or *sl*. This is optional since it is only used when stack checking is enabled.
- The BLLO instruction is a branch with link instruction plus the condition mnemonic LO.
 - If sp is less than register r10 after the new items are pushed onto the stack, then *stack* overflow error has occurred.
 - If the stack pointer goes back past the stack base, then a *stack underflow* error has occurred.

Swap Instruction:

The swap instruction is a special case of a load-store instruction. It swaps the contents of memory with the contents of a register.

This instruction is an *atomic operation*—it reads and writes a location in the same bus operation, preventing any other instruction from reading or writing to that location until it completes.

Syntax: SWP{B}{<cond>} Rd,Rm,[Rn]

SWP	swap a word between memory and a register	tmp = mem32[Rn] mem32[Rn] = Rm Rd = tmp
SWPB	swap a byte between memory and a register	tmp = mem8[Rn] mem8[Rn] = Rm Rd = tmp

Swap cannot be interrupted by any other instruction or any other bus access. We say the system "holds the bus" until the transaction is complete. Also, swap instruction allows for both a word and a byte swap.

Example: The swap instruction loads a word from memory into register r0 and overwrites the memory with register r1.

```
PRE mem32[0x9000] = 0x12345678

r0 = 0x00000000

r1 = 0x11112222

r2 = 0x00009000

SWP r0, r1, [r2]

POST mem32[0x9000] = 0x11112222

r0 = 0x12345678

r1 = 0x11112222

r2 = 0x00009000
```

Example: This example shows a simple data guard that can be used to protect data from being written by another task. The SWP instruction "holds the bus" until the transaction is complete.

spin

```
MOV r1, =semaphore
MOV r2, #1
SWP r3, r2, [r1] ; hold the bus until complete
CMP r3, #1
BEQ spin
```

MAHESH PRASANNA K., VCET, PUTTUR

15CS44

15CS44

MICROPROCESSORS AND MICROCONTROLLERS

The address pointed to by the semaphore either contains the value 0 or 1. When the semaphore equals 1, then the service in question is being used by another process. The routine will continue to loop around until the service is released by the other process—in other words, when the semaphore address location contains the value 0.

SOFTWARE INTERRUPT INSTRUCTION:

A *software interrupt instruction (SWI)* causes a software interrupt exception, which provides a mechanism for applications to call operating system routines.

Syntax: SWI{<cond>} SWI number

SWI	software interrupt	lr_svc = address of instruction following the SWI
		spsr_svc = cpsr
		$spsr_svc = cpsr$ pc = vectors + 0x8
		cpsr mode = SVC
		cpsr I = 1 (mask IRQ interrupts)

When the processor executes an SWI instruction, it sets the program counter pc to the offset 0x8 in the vector table. The instruction also forces the processor mode to SVC, which allows an operating system routine to be called in a privileged mode.

Each SWI instruction has an associated SWI number, which is used to represent a particular function call or feature.

Example: Here we have a simple example of an SWI call with SWI number 0x123456, used by ARM toolkits as a debugging SWI. Typically the SWI instruction is executed in user mode.

 $PRE \quad cpsr = nzcVqift_USER$ pc = 0x00008000 $lr = 0x003fffff \qquad ; lr = r14$ r0 = 0x12 $0x00008000 \quad SWI \quad 0x123456$ $POST \quad cpsr = nzcVqIft_SVC$ $spsr = nzcVqift_USER$ pc = 0x0000008 lr = 0x0000008 r0 = 0x12

Since SWI instructions are used to call operating system routines, you need some form of parameter passing. This is achieved using registers. In this example, register r0 is used to pass the parameter 0x12. The return values are also passed back via registers.

15CS44

MICROPROCESSORS AND MICROCONTROLLERS

Code called the *SWI handler* is required to process the SWI call. The handler obtains the SWI number using the address of the executed instruction, which is calculated from the link register *lr*. The SWI number is determined by

SWI_Number = <SWI instruction> AND NOT (0xff000000)

Here the SWI instruction is the actual 32-bit SWI instruction executed by the processor.

Example: This example shows the start of an SWI handler implementation. The code fragment determines what SWI number is being called and places that number into register r10.

You can see from this example that the load instruction first copies the complete SWI instruction into register r10. The BIC instruction masks off the top bits of the instruction, leaving the SWI number. We assume the SWI has been called from ARM state.

SWI_handler

; Store registers r0-r12 and the link register

STMFD sp!, {r0-r12, lr}

; Read the SWI instruction

LDR r10, [lr, #–4]

; Mask off top 8 bits

BIC r10, r10, #0xff000000

; r10 - contains the SWI number

BL service_routine

; return from SWI handler

LDMFD sp!, {r0-r12, pc}^

The number in register r10 is then used by the SWI handler to call the appropriate SWI service routine.

PROGRAM STATUS REGISTER INSTRUCTIONS:

The ARM instruction set provides two instructions to directly control a program status register (psr).

- ✓ The *MRS instruction* transfers the contents of either the *cpsr* or *spsr* into a register.
- ✓ The *MSR instruction* transfers the contents of a register into the *cpsr* or *spsr*.

Together these instructions are used to read and write the cpsr and spsr.

In the syntax we can see a *label* called fields. This can be any combination of *control* (*c*), *extension* (*x*), *status* (*s*), and *flags* (*f*).

```
Syntax: MRS{<cond>} Rd,<cpsr|spsr>
    MSR{<cond>} <cpsr|spsr>_<fields>,Rm
    MSR{<cond>} <cpsr|spsr> <fields>,#immediate
```

MRS	copy program status register to a general-purpose register	Rd = psr
MSR	move a general-purpose register to a program status register	psr[field] = Rm
MSR	move an immediate value to a program status register	psr[field] = immediate

These fields relate to particular byte regions in a psr, as shown in the following Figure.

Figure: psr Byte Fields

The c field controls the interrupt masks, Thumb state, and processor mode.

The following Example shows how to enable IRQ interrupts by clearing the *I* mask. This operation involves using both the MRS and MSR instructions to read from and then write to the *cpsr*.

Example: The MSR first copies the *cpsr* into register r1. The BIC instruction clears bit 7 of r1. Register r1 is then copied back into the *cpsr*, which enables IRQ interrupts. You can see from this example that this code preserves all the other settings in the *cpsr* and only modifies the *I* bit in the control field.

PRE cpsr = nzcvqIFt_SVC
MRS r1, cpsr
BIC r1, r1, #0x80 ; 0b01000000
MSR cpsr_c, r1
POST cpsr = nzcvqiFt_SVC

15CS44

This example is in SVC mode. In user mode you can read all cpsr bits, but you can only update the condition flag field f.

Coprocessor Instructions:

Coprocessor instructions are used to extend the instruction set.

- ✓ A coprocessor can either provide additional computation capability or be used to control the memory subsystem including caches and memory management.
- ✓ The coprocessor instructions include data processing, register transfer, and memory transfer instructions.
- \checkmark Note that these instructions are only used by cores with a coprocessor.

CDP	coprocessor data processing-perform an operation in a coprocessor
MRC MCR	coprocessor register transfer-move data to/from coprocessor registers
LDC STC	coprocessor memory transfer-load and store blocks of memory to/from a coprocessor

- \checkmark In the syntax of the coprocessor instructions,
 - The cp field represents the coprocessor number between p0 and p15
 - The *opcode* fields describe the operation to take place on the coprocessor.
 - The Cn, Cm, and Cd fields describe registers within the coprocessor.
- \checkmark The coprocessor operations and registers depend on the specific coprocessor you are using.
- ✓ Coprocessor 15 (CP15) is reserved for system control purposes, such as memory management, write buffer control, cache control, and identification registers.

Example: This example shows a CP15 register being copied into a general-purpose register.

; transferring the contents of CP15 register c0 to register r10

MRC p15, 0, r10, c0, c0, 0

Here *CP15 register-0* contains the processor identification number. This register is copied into the general-purpose register r10.

LOADING CONSTANTS:

15CS44

You might have noticed that there is no ARM instruction to move a 32-bit constant into a register. Since ARM instructions are 32 bits in size, they obviously cannot specify a general 32-bit constant.

To aid programming there are two pseudo-instructions to move a 32-bit value into a register.

```
Syntax: LDR Rd, =constant
ADR Rd, label
```

LDR	load constant pseudoinstruction	Rd = 32-bit constant
ADR	load address pseudoinstruction	Rd = 32-bit relative address

- The first pseudo-instruction writes a 32-bit constant to a register using whatever instructions are available. It defaults to a memory read if the constant cannot be encoded using other instructions.
- The second pseudo-instruction writes a relative address into a register, which will be encoded using a pc-relative expression.

15CS44

MICROPROCESSORS AND MICROCONTROLLERS

Example: This example shows an LDR instruction loading a 32-bit constant 0x ff00ffff into register r0.

LDR r0, [pc, #constant_number-8-{PC}]

:

constant_number

DCD 0xff00ffff

This example involves a memory access to load the constant, which can be expensive for time-critical routines.

The following Example shows an alternative method to load the same constant into register r0 by using an MVN instruction.

Example: Loading the constant *0xff00ffff* using an MVN.

PRE none...

MVN r0, #0x00ff0000

POST r0 = 0xff00ffff

As you can see, there are alternatives to accessing memory, but they depend upon the constant you are trying to load.

The LDR pseudo-instruction either inserts an MOV or MVN instruction to generate a value (if possible) or generates an LDR instruction with a *pc*-relative address to read the constant from a literal pool—a data area embedded within the code.

The following Table shows two pseudo-code conversions.

PseudoinstructionActual instructionLDR r0, =0xffMOV r0, #0xffLDR r0, =0x55555555LDR r0, [pc, #offset 12]

Table: LDR pseudo-instruction Conversion

The first conversion produces a simple MOV instruction; the second conversion produces a *pc*-relative load.

Another useful pseudo-instruction is the ADR instruction, or address relative. This instruction places the address of the given label into register Rd, using a pc-relative add or subtract.

By: MAHESH PRASANNA K.,

DEPT. OF CSE, VCET.
